Finding Chemical Reactions

Which paths do molecules take?

START

A chemical reaction is a rearrangement of building blocks, much like when playing with toy bricks. Here, we have one atom of carbon (C) and four atoms of hydrogen (H) combined into the molecule methane (CH_4), as well as two times two atoms of oxygen (O) combined into oxygen gas (O_2).

Let's see what we get when we rearrange them!

To rearrange atoms into different molecules, bonds between atoms need to be broken first. This requires energy, and so every chemical reaction has to overcome a barrier. The stronger the bond, the higher the barrier, and so the more difficult the reaction is.

Most atoms will not stay disconnected and will almost immediately react with each other to form molecules. Therefore, the disconnected state has the highest energy. This is the barrier that needs to be overcome for a reaction to happen.

Like sledging down a hill, chemical reactions proceed naturally from molecules with higher energy levels to ones with lower energy levels. Note that the starting compounds are higher up than the end products!

The starting compounds can also be rearranged into in one molecule of formaldehyde (CH_2O), one molecule of water (H_2O) and one molecule of oxygen gas (O_2). This almost never happens naturally, but by carefully controlling the reaction conditions, this can be made the main outcome.

Chemical reactions are everywhere. Whenever matter is transformed from one form to another, a chemical reaction is the cause, for example when we breathe, cook, or when we make drugs or materials. At ICReDD, we are developing a new way of finding entirely new chemical reactions to make making everything possible. So, what is a chemical reaction?

Our reaction burned the methane and resulted in one molecule of carbon dioxide (CO_2) and two molecules of water (H_2O). Note that the end products have properties very different from the starting compounds, but are made up of the same atoms!

GOAL

Level

1

Rearrangements

All things are made of atoms. There are a limited number of different atoms, but they can bond with each other in infinitely many ways. The resulting structures, called molecules, have properties that depend on the arrangement of the atoms they are made of. A chemical reaction is a rearrangement of atoms through forming or breaking the bonds between them, giving rise to molecules with properties very different from what we started with.

Level

3

Breaking Bonds

The right placement of the right amount of energy is so crucial because the bonds between atoms are maintained by electrons that are held in place by a balance of attraction to the atoms' nuclei and repulsion by other electrons. If atoms need to be rearranged, the repulsion between specific electrons needs to be overcome. Only then can chemical reactions be realized purposefully.

Level

2

Activation Energy

To explain why some chemical reactions happen almost spontaneously while others don't, we assign a property to each molecule that we call "chemical energy". A chemical reaction proceeds naturally if it transforms a molecule of higher energy to one of lower energy, whereas energy has to be put into a reaction to proceed from molecules of lower to higher energy. But before they can happen, all chemical reactions first need a little extra energy, because the chemical bonds need to be broken before they can be rearranged. The crucial point of all chemical engineering is how to transfer the right amount of energy to the right place in a molecule so that specific bonds can be broken and formed.

Level

4

Potential Energy Surface

Every little change of the state of an electron can be assigned an

energy. Therefore, all rearrangements of electrons are chemical reactions. And if we can calculate all energy levels of all electronic rearrangements, it should be possible to know exactly how much energy is needed where to make every chemical reaction possible—and to produce everything. This is the dream of ICRéDD.

Activation

Quiz

What is the oldest chemical reaction used by humans?
Send us your answer.

Challenge

Arrange the things on your desk to make something. Try to combine the same objects into two or three different things. What did you make?

Share your answer

Researcher Profile

Yuichi KITAGAWA

This is Yuichi Kitagawa.
He works on
Europium complexes that
can emit very bright red light
when illuminated with
UV or blue light.

Short biography

Specially Appointed Lecturer at ICReDD
and Faculty of Engineering, Hokkaido
University

After his Ph.D. from the University of
Tokyo in 2013, a JSPS Research Fellow at
Ritsumeikan University. From May 2014,
a Specially Appointed Assistant Professor
at the Faculty of Engineering, Hokkaido
University. Current position since April
2019. He specializes in photochemistry.

About ICRéDD

The development of new chemical reactions is intrinsically entangled with the prosperity of humanity and the preservation of the environment. A recent example of such transformative chemical reactions with profound impact is cross-coupling reactions, the discovery of which was awarded with the 2010 Nobel Prize in Chemistry. These reactions are used to produce approximately 20% of all medicinal reagents, and almost all liquid crystalline and organic electroluminescent materials. The industrial use of these chemical reactions contributes ~60 trillion yen per annum to the global economy. The development of new chemical reactions thus significantly affects the evolution of society.

ICRéDD is the Institute for Chemical Reaction Design and Discovery, a WPI center at Hokkaido University where researchers from different disciplines combine their strengths to take full control over chemical reactions. The institute was born out of the realization that the purposeful design of chemical reactions requires cross-sectional collaborations at every step. Working on such a fundamental natural process, quantum-chemical computations, information technology, modern experimental techniques, and the development of advanced materials can no longer be separate fields if we want to achieve significant breakthroughs. Rather, they have to become part of a diverse toolbox for truly integrated research.

The Catalyst is inspired by catalysts used in chemistry to bring molecules together, to reduce reaction barriers, and to activate molecules—to make reactions happen faster. In this spirit, this poster series should enable its readers to make the connection between chemical reactions and the wellbeing of our society, and to look at the world in a new way, seeing how chemical reactions and chemistry shape the world around them. And if we can take this opportunity to introduce ourselves, too, this may also catalyze new friendships and opportunities. #ReactWithUs
